DGP: iid  $U(0, \theta)$

We want to find the MM estimator for  $\theta$

$$\mu_1 = E[X] = \frac{0+\theta}{2} = \frac{\theta}{2} = \alpha_1(\theta) \Rightarrow \theta = 2\mu = 8, (\mu_1)$$

$$\Rightarrow \hat{\theta}^{MM} = 2\hat{\mu}_1 = 2\bar{X}$$

Data:  $\vec{X} = \langle 1, 2, 3, 107 \rangle, \hat{\theta}^{MM} = 2\bar{X} = 2(4) = 8$

This is an absurd estimate. We're saying the true population maximum is 8 but we've already seen  $x_4 = 107 > 8$ !! So this is clearly nonsensical.

Another method for finding estimates/estimation goes back to the 1800's but was popularized by Fisher between 1912-1922 and it's called "maximum likelihood".

$$x_1, \dots, x_n \stackrel{\text{iid}}{\sim} \text{DGP}(\theta_1, \dots, \theta_k) \quad \begin{matrix} P(x_i, \theta_1, \dots, \theta_k) \text{ if discrete} \\ \text{default} \\ f(x_i, \theta_1, \dots, \theta_k) \text{ if continuous} \end{matrix}$$

$$\prod_{i=1}^n L(\theta_1, \dots, \theta_k; x_i)$$

Due to independence and identical distributedness

likelihood =  $L(\theta_1, \dots, \theta_k; x_1, \dots, x_n) \stackrel{\text{density}}{=} f(x_1, \dots, x_n; \theta_1, \dots, \theta_k) = \prod_{i=1}^n f(x_i; \theta_1, \dots, \theta_k)$

"stat perspective" // inputs / given variables      inputs given variables

"L" variables      variables

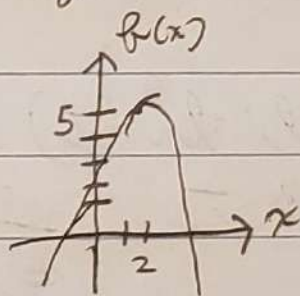

Note:  $f > 0$  (density)  $\Rightarrow L > 0$

We now vary  $\theta_1, \dots, \theta_k$  and try to find the values that maximize the likelihood ( $L$ ) and those values of the  $\theta$  are called the "maximum likelihood estimate(s)" (MLE).

$$\hat{\theta}_1^{MLE}, \dots, \hat{\theta}_k^{MLE} := \underset{(H)}{\operatorname{argmax}} (L) = \operatorname{argmax} \left\{ \prod_{i=1}^n L(\theta_1, \dots, \theta_k; x_i) \right\}$$

The "argmax" operator computes the arguments that create the maximum value of the function eg

$$f(x) = -x^2 + 4x + 1 = -(x-2)^2 + 5$$

$$\max \{ f(x) \} = 5, \operatorname{argmax} \{ f(x) \} :=$$

$$\{ x : f(x) = \max \{ f(x) \} \} = 2$$

How to find an argmax. Take  $f'(x) = 0$  and then ensure the second derivative at that value is negative

$$f'(x) = -2x + 4 \stackrel{\text{set}}{=} 0 \Rightarrow x_* = 2 \leftarrow \operatorname{argmax}$$

$$f''(x) = -2, f''(2) = -2 < 0 \checkmark$$

The argmax is unaffected by taking a strictly increasing function  $g$  of the set being analyzed is

$$\operatorname{argmax} \{f(x)\} = \operatorname{argmax} \{g(f(x))\}$$

$$\frac{d}{dx} [g(f(x))] = \underbrace{g'(f(x))}_{>0} f'(x) \stackrel{\text{set}}{=} 0 \Rightarrow f'(x) = 0 \Rightarrow x^*$$

Note that  $g(x) = \ln(x)$  is a strictly increasing function  $x > 0$

$$\begin{aligned} \hat{\theta}_1^{MLE}, \dots, \hat{\theta}_K^{MLE} &= \operatorname{argmax}_{\theta_1, \dots, \theta_K} \{ \ln(L) \} \stackrel{iid}{=} \operatorname{argmax} \left\{ \ln \left( \prod_{i=1}^n L(\theta_1, \dots, \theta_K; x_i) \right) \right\} \\ &= \operatorname{argmax}_{\theta_1, \dots, \theta_K} \left\{ \sum_{i=1}^n \ln(L(\theta_1, \dots, \theta_K; x_i)) \right\} \\ &\stackrel{\text{def}}{=} \operatorname{argmax}_{\theta_1, \dots, \theta_K} \left\{ \sum_{i=1}^n \ell(\theta_1, \dots, \theta_K; x_i) \right\} \end{aligned}$$

Why do this whole natural log thing? Well ... because we're going to take the derivative of the expression inside the argmax to find the argmax and taking derivatives of sums is easy because the derivative operator is linear.

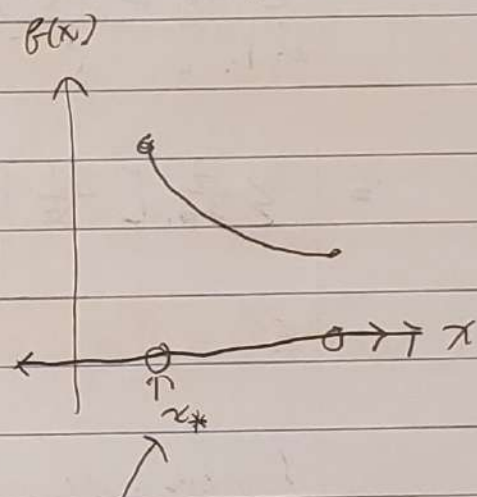

To get the MLE's, we solved the following system of equations:

$$\sum_{i=1}^n \frac{\partial}{\partial \theta} [l(\theta, \dots, \theta_k; x_i)] \stackrel{\text{seq}}{=} 0$$

add to  
previous section  
↑

$$\sum_{i=1}^n \frac{\partial}{\partial \theta_2} [l(\theta, \dots, \theta_k; x_i)] \stackrel{\text{seq}}{=} 0$$

$$\sum_{i=1}^n \frac{\partial}{\partial \theta_k} [l(\theta, \dots, \theta_k; x_i)] \stackrel{\text{seq}}{=} 0$$

It's also possible, there is no maximum that corresponds to a critical point. So then you have to check the "edges" of the parameter space manually

DGP:  $x_1, \dots, x_n \stackrel{iid}{\sim} \text{Bern}(\theta)$ , find  $\hat{\theta}^{MLE}$

$$\sum_{i=1}^n \frac{d}{d\theta} [l(\theta; x_i)] = \sum_{i=1}^n \frac{d}{d\theta} [\ln(p(x_i; \theta))] = \sum_{i=1}^n \frac{d}{d\theta} [\ln(\theta^{x_i} (1-\theta)^{1-x_i})]$$

$$= \sum_{i=1}^n \frac{d}{d\theta} [x_i \ln(\theta) + (1-x_i) \ln(1-\theta)] = \sum_{i=1}^n \frac{x_i}{\theta} - \frac{1-x_i}{1-\theta} = \frac{\sum x_i}{\theta} - \frac{n - \sum x_i}{1-\theta}$$

$$\Rightarrow \frac{\sum x_i}{\theta} = \frac{n - \sum x_i}{1-\theta} \Rightarrow (1-\theta) \sum x_i = \theta (n - \sum x_i)$$

$$\Rightarrow \sum x_i - \theta \leq x_i = \theta_n - \theta \leq x_i \Rightarrow \hat{\theta}^{MLE} = \bar{X}$$

PGP:  $x_1, \dots, x_n \stackrel{iid}{\sim} N(\theta_1, \theta_2)$ . Find MLE's for  $\theta_1$  and  $\theta_2$

$$\sum_{i=1}^n \frac{\partial}{\partial \theta_1} [\ln(f)] = \sum_{i=1}^n \frac{\partial}{\partial \theta_1} \left[ \ln \left( \frac{1}{\sqrt{2\pi}\theta_2} e^{-\frac{1}{2\theta_2}(x_i - \theta_1)^2} \right) \right]$$

$$= \sum_{i=1}^n \frac{\partial}{\partial \theta_1} \left[ -\frac{1}{2} \ln(2\pi) - \frac{1}{2} \ln(\theta_2) - \frac{1}{2\theta_2} (x_i - \theta_1)^2 \right]$$

$$\Downarrow$$

$$= \sum_{i=1}^n \left[ -\frac{x_i^2}{2\theta_2} + \frac{x_i \theta_1}{\theta_2} - \frac{\theta_1^2}{2\theta_2} \right]$$

$$= \sum \frac{x_i}{\theta_2} - \frac{\theta_1}{\theta_2} = \frac{\sum x_i}{\theta_2} - \frac{n\theta_1}{\theta_2} \stackrel{\text{set}}{=} 0 \Rightarrow \hat{\theta}_1^{MLE} = \bar{X}$$

Now for  $\hat{\theta}_2^{MLE}$

$$\sum \frac{\partial}{\partial \theta_2} \left[ -\frac{1}{2} \ln(2\pi) - \frac{1}{2} \ln(\theta_2) - \frac{(x_i - \theta_1)^2}{2\theta_2} \right]$$

$$= \sum \left[ -\frac{1}{2\theta_2} + \frac{(x_i - \theta_1)^2}{2\theta_2^2} \right] = -\frac{n}{2\theta_2} + \frac{\sum (x_i - \theta_1)^2}{2\theta_2^2} \stackrel{\text{set}}{=} 0$$

$$\Rightarrow \sum (x_i - \theta_1)^2 = n\theta_2 \Rightarrow \hat{\theta}_2^{MLE} = \frac{1}{n} \sum (x_i - \theta_1)^2 \stackrel{\text{plug in}}{\Rightarrow} \hat{\theta}_2^{MLE} = \frac{1}{n} \sum (x_i - \hat{\theta}_1^{MLE})^2$$

$$\Rightarrow \hat{\theta}_2^{MLE} = \frac{1}{n} \sum (x_i - \bar{X})^2 = \hat{\sigma}^2 \neq S^2$$

$$\hat{\theta}^{MLE} = w(x_1, \dots, x_n) \Leftrightarrow \hat{\theta}^{MLE} = w(x_1, \dots, x_n) \text{ maximum likelihood estimator}$$

Maximum likelihood estimate

$$\hat{\theta}^{MM} = w(x_1, \dots, x_n) \Leftrightarrow \hat{\theta}^{MM} = w(x_1, \dots, x_n)$$

$$DGP: x_1, \dots, x_n \stackrel{iid}{\sim} U(0, \theta), \hat{\theta}^{MM} = 2\bar{x}, \hat{\theta}^{MLE} = ?$$

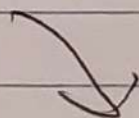

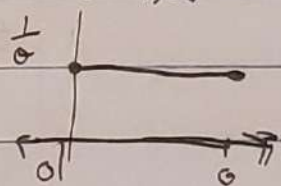

$$\leq \frac{d}{d\theta} [\ell(\theta; x_i)] = \leq \frac{d}{d\theta} [\ln(f(x_i; \theta))] = \leq \frac{d}{d\theta} [\ln(\frac{1}{\theta})] =$$

$$\leq \frac{d}{d\theta} = [-\ln(\theta)]$$

$$= \sum_{i=1}^n -\frac{1}{\theta} = -\frac{n}{\theta} \stackrel{\text{set}}{=} 0 \Rightarrow \text{no solution}$$

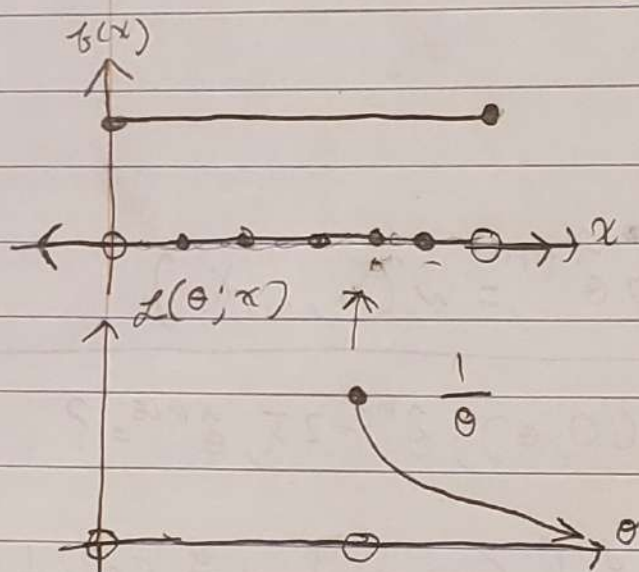

$$\prod_{i=1}^n f(x_i; \theta) = \prod_{i=1}^n \begin{cases} \frac{1}{\theta} & \text{if } 0 \leq x_i \leq \theta \\ 0 & \text{o/t "nothing"} \end{cases}$$

$$\rightarrow = \begin{cases} \frac{1}{\theta^n} & \text{if } 0 \leq x_i \leq \theta \forall x_i \\ 0 & \text{o/t "nothing"} \end{cases}$$

$$\prod_{i=1}^n L(\theta; x_i) = \prod_{i=1}^n \begin{cases} \frac{1}{\theta} & \theta \geq x_i \\ 0 & \text{otherwise} \end{cases} = \begin{cases} \frac{1}{\theta^n} & \text{if } \theta \geq x_i \forall x_i \\ 0 & \text{otherwise} \end{cases}$$

$$\hat{\theta}^{MLE} = \max \{x_1, \dots, x_n\}$$

$$\hat{\theta}^{MLE} = \max \{x_1, \dots, x_n\}$$

Beyond scope of course from 368 we know that...

$$\hat{\theta}^{MLE} \sim \text{Scaled Beta}(n, 1, \theta) \Rightarrow \text{Var}[\hat{\theta}^{MLE}] = \theta^2 \frac{n}{(n+1)^2(n+2)}$$

$$\hat{\theta}^{MM} = 2\bar{x} \sim ? \Rightarrow \text{Var}[2\bar{x}] = 4 \frac{\text{Var}[x]}{n} = 4 \frac{(\theta - 0)^2}{12n}$$

∴

$$\theta^2 \frac{1}{3n}$$

∴ we can now compare the variance of two different estimators
